

Analysis of Algorithms 2020/2021

Practice 1

Sofia Xiao Fernandez Marin, 1292.

Code	Plots	Memory	Total

1. Introduction.

In this practice we have to write code and implement several functions to generate permutations of numbers and later use those permutations to prove sorting algorithms functions.

2. Objectives

2.1 Section 1

In this part, we have learnt how to use the rand and srand function to create a routine that generates equiprobable random numbers between the values we provide to the routine. In our case, we have chosen to generate just positive numbers, not negative ones.

2.2 Section 2

In this section we have implemented a function able to create random permutations based on a given table.

2.3 Section 3

After creating the function that generates random permutations, we need to code another function that, calling the previous one, generates a matrix of equiprobable permutations.

2.4 Section 4

In this part we implemented the function InsertSort, that sorts the elements of a given table of random numbers. It returns the number of times the basic operation has been executed.

2.5 Section 5

In this section we have implemented three different functions to measure the execution time and the basic operations of the sorting algorithm InsertSort.

2.6 Section 6

Finally, we have created the function InsertSortInv, to sort a table in a descendant way, and to compare the results between this function and the InsertSort function.

3 Tools and Methodology

Basically, the tool that we have been using during this task is Visual Studio Code, because it facilitates us the debugging of the code. We have also executed all the exercises with valgrind to prove that there were no dynamic memory allocation errors.

3.1 Section 1

In this first exercise we looked for information about the rand and srand functions to know better their functionality, and then we fit the values in rand to generate equiprobable random numbers between the values given to the random_num function.

We have done it searching on the internet for different ways to implement this and that finally gave us the idea of doing it as we do it.

3.2 Section 2

To do this exercise, that consisted in implementing the generate_perm function, we just transformed the given pseudocode into C code, and then we proved with valgrind that memory allocation was in order.

3.3 Section 3

In this case, we have to create a matrix of permutations. So, we reserved memory for the double pointer and then we initialized each line of the matrix calling the previous function generate_perm. We also checked memory errors with valgrind.

3.4 Section 4

Here we implemented the function InsertSort. The teacher helped us with the pseudocode in class, so it was not so difficult. The code we implemented starts the loop in the second element of the table, so that a number doesn't swap with each self.

3.5 Section 5

In this section, we first implemented the function average_sorting_time, that first creates a table of permutations, then it sorts each line of the table through a loop that goes through the lines and call the method for each of them. We also used the function clock to establish the time it takes to sort. At the end of the program we free the table to avoid errors.

Then, we implemented the function generate_sorting_times. Where first we obtained the number of permutations we are going to work on. Then we reserved memory for a structure of time for each permutation to save the executing information about each permutation. Then we generated the permutations and saved them in the corresponding structures. Finally, we called the function save_time_table to write in a file all the information of each permutation.

3.6 Section 6

In this last section, we implemented the function InsertSortInv in the sorting.c file. This function was implemented similar as in InsertSort but sorting a list of numbers in reverse order.

4. Source code

4.1 Section 1

```
int random_num(int inf, int sup){

    int random = 0;

    if (sup < inf || inf < 0 || sup > RAND_MAX) return ERR;

    random = (int) inf + rand() / ((RAND_MAX + 1.0) / (sup - inf + 1));

    return random;
}
```

4.2 Section 2

```
int* generate_perm(int N){

    int i = 0, num1 = 0, num2 = 0;
    int *perm = NULL;

    if (N <= 0) return NULL;

    perm = (int*) malloc ( N * sizeof(perm[0]));
    if (perm == NULL) return NULL;

    for (i = 0; i < N; i++){
        perm[i] = i + 1;
    }

    for (i = 0; i < N; i++){
        num1 = perm[i];
        num2 = random_num(i, N-1);
        perm[i] = perm[num2];
        perm[num2] = num1;
    }

    return perm;
}
```

4.3 Section 3

```
int** generate_permutations(int n_perms, int N) {

    int **perm = NULL;
    int i=0;

    if (n_perms <= 0 || N <= 0) return NULL;

    perm = (int**) calloc ((n_perms), sizeof(perm[0]));
    if (perm == NULL) return NULL;

    for (i = 0; i < n_perms; i++){
        perm [i]= generate_perm(N);

        if (perm[i] == NULL) {
            for (i = i-1; i >= 0; i--) {
                free (perm[i]);
            }
            free(perm);
            return NULL;
        }

    }

    return perm;
}
```

4.4 Section 4

```
int InsertSort(int *table, int ip, int iu){

    int i = 0, j = 0, aux = 0, cont = 0;

    if (table == NULL || ip < 0 || iu < ip) return ERR;

    for (i = ip + 1; i <= iu; i++){
        aux = table[i];
        j = i - 1;
        while (j >= ip && table[j] > aux){
            table[j + 1] = table[j];
            j--;
            cont++;
        }

        if (j>=ip) cont++;
        table[j + 1] = aux;
    }

    return cont;
}
```

4.5 Section 5

```
short average_sorting_time(pfunc_sort method, int n_perms, int N, PTIME_AA ptime){

    clock_t time1 = 0, time2 = 0;
    int i = 0, j = 0, time_ob = 0, ob=0;

        if(fprintf(f, "\n") < 0) return ERR;
    }

    if(fclose(f)!=0) return ERR;

    return OK;
}

```

4.6 Section 6

```

int InsertSortInv(int *table, int ip, int iu){

    int i = 0, j = 0, aux = 0, cont = 0;

    if (table == NULL || ip < 0 || iu < ip) return ERR;

    for (i = ip + 1; i <= iu; i++){
        aux = table[i];
        j = i - 1;
        while (j >= ip && table[j] < aux){
            table[j + 1] = table[j];
            j--;
            cont++;
        }
        if (j>=ip) cont++;
        table[j + 1] = aux;
    }
    return cont;
}

```

5. Results, Plots

5.1 Section 1

As we can see, there is a straight line because the numbers appear the same time.

5.2 Section 2

5.6 Section 6

5. Answers to theoretical Questions.

5.1 Question 1

We looked in the Internet information about how the rand function works and then we realized we had to change the range 0 - RANDMAX by using the formula:

```
random = (int) inf + rand() / ((RAND_MAX + 1.0) / (sup - inf + 1));
```

5.2 Question 2

This algorithm picks the second element of a table and after that it compares it with the one that has at his left.

If it is greater than the one that is in the second position it changes it. If not, the third element is picked, and it is compared with the second one. If the picked element is greater, it changes it and if not, it compares the chosen element with the following (the element that is on the left side of the one that it was compared to). It keeps going to the fourth and the rest of the table.

The element that its chosen is compared with the left element that it has. If the element of its left is greater it changes its position. If not, it goes to the left element of the one that has been compared with the chosen one.

The algorithm works well because it writes in each subtable and in each iteration the smallest element in the first position, after comparing it with the rest of the elements in the table, but just swapping it once.

5.3 Question 3

The outer loop of InsertSort does not act on the first element of the table because then it would not have an element on its left to compare with.

5.4 Question 4

It is a loop that executes in each operation:

```
table [j] > aux
```

5.5 Question 5

$W_{BS}(n) : \text{InsertSort}(\sigma) = (N^2 / 2) + O(N)$

$B_{BS}(n) : \text{InsertSort}(\sigma) (N-1)$

The simplest worst case input is an array sorted in reverse order.

The best case input is an array that is already sorted. In this case insertion sort has a linear.

5.5 Question 6

As shown in the plots, the execution times for InsertSort and InsertSortInv are almost the same. This is because the order in which we want to sort the table does not affect the algorithm, because the mechanism is the same with the only difference that it looks for the biggest element instead of the smallest one.

6. Final Conclusions.

In general, this assignment has been interesting, because we first coded the algorithms to create tables of permutations and then we could see the results when doing the plots.

It was not something new for us because in theory class they have told us about the times and basic operations and before the practice we knew what the result was going to be, but it has been nice to see it and prove it by ourselves.
